Learning Fully Observed Undirected Graphical Models

Kayhan Batmanghelich

Slides Credit: Matt Gormley (2016)
Machine Learning

The **data** inspires the structures we want to predict.

Our **model** defines a score for each structure.

It also tells us what to optimize.

**Inference** finds \{best structure, marginals, partition function\} for a new observation.

**Learning** tunes the parameters of the model.

(Inference is usually called as a subroutine in learning)
MLE for Undirected GMs

1. Data
\[ \mathcal{D} = \{ \mathbf{x}^{(n)} \}_{n=1}^{N} \]

2. Model
\[ p(\mathbf{x} | \theta) = \frac{1}{Z(\theta)} \prod_{C \in \mathcal{C}} \psi_C(\mathbf{x}_C) \]

3. Objective
\[ \ell(\theta; \mathcal{D}) = \sum_{n=1}^{N} \log p(\mathbf{x}^{(n)} | \theta) \]

4. Learning
\[ \theta^* = \arg\max_{\theta} \ell(\theta; \mathcal{D}) \]

5. Inference
1. Marginal Inference
\[ p(\mathbf{x}_C) = \sum_{\mathbf{x}': \mathbf{x}'_C = \mathbf{x}_C} p(\mathbf{x}' | \theta) \]
2. Partition Function
\[ Z(\theta) = \sum_{\mathbf{x}} \prod_{C \in \mathcal{C}} \psi_C(\mathbf{x}_C) \]
1. Data

Given training examples: \[ D = \{ \mathbf{x}^{(n)} \}_{n=1}^{N} \]

Sample 1:
- \( n \): time
- \( v \): flies
- \( p \): like
- \( d \): an
- \( n \): arrow

Sample 2:
- \( n \): time
- \( n \): flies
- \( v \): like
- \( d \): an
- \( n \): arrow

Sample 3:
- \( n \): flies
- \( v \): fly
- \( p \): with
- \( n \): their
- \( n \): wings

Sample 4:
- \( p \): with
- \( n \): time
- \( n \): you
- \( v \): will
- \( v \): see

2. Model
2. Model

Define the model to be an MRF:

\[
p(\mathbf{x} \mid \theta) = \frac{1}{Z(\theta)} \prod_{C \in \mathcal{C}} \psi_C(\mathbf{x}_C)
\]

3. Objective

Choose the objective to be log-likelihood:

\[
\ell(\theta; \mathcal{D}) = \sum_{n=1}^{N} \log p(\mathbf{x}^{(n)} \mid \theta)
\]

(Assign high probability to the things we observe and low probability to everything else)
3. Objective

Choose the objective to be log-likelihood:

\[
\ell(\theta; \mathcal{D}) = \sum_{n=1}^{N} \log p(x^{(n)} | \theta)
\]

(Assign high probability to the things we observe and low probability to everything else)

4. Learning

Tune the parameters to maximize the objective function

\[
\theta^* = \arg \max_{\theta} \ell(\theta; \mathcal{D})
\]
3. Objective

Choose the objective to be log-likelihood:

\[ \log p(x_n | \theta) \]

(Assign high probability to the things we observe and low probability to everything else)

Goals for Today’s Lecture

1. Optimize this objective function
2. Characterize the applicability of different optimizers

\[ \theta^* = \arg\max_{\theta} \ell(\theta; D) \]
5. Inference

Three Tasks:

1. Marginal Inference
   Compute marginals of variables and cliques
   \[ p(x_i) = \sum_{x'_i:x'_i = x_i} p(x' | \theta) \quad | \quad p(x_C) = \sum_{x':x'_C = x_C} p(x' | \theta) \]

2. Partition Function
   Compute the normalization constant
   \[ Z(\theta) = \sum_{x} \prod_{C \in C} \psi_C(x_C) \]

3. MAP Inference
   Compute variable assignment with highest probability
   \[ \hat{x} = \arg\max_x p(x | \theta) \]
MLE for Undirected GMs

1. Data
\[ \mathcal{D} = \{ \mathbf{x}^{(n)} \}_{n=1}^{N} \]

2. Model
\[ p(\mathbf{x} \mid \theta) = \frac{1}{Z(\theta)} \prod_{C \in \mathcal{C}} \psi_C(\mathbf{x}_C) \]

3. Objective
\[ \ell(\theta; \mathcal{D}) = \sum_{n=1}^{N} \log p(\mathbf{x}^{(n)} \mid \theta) \]

4. Learning
\[ \theta^* = \arg\max_{\theta} \ell(\theta; \mathcal{D}) \]

5. Inference
1. Marginal Inference
\[ p(\mathbf{x}_C) = \sum_{\mathbf{x}' : \mathbf{x}'_{C} = \mathbf{x}_C} p(\mathbf{x}' \mid \theta) \]
2. Partition Function
\[ Z(\theta) = \sum_{\mathbf{x}} \prod_{C \in \mathcal{C}} \psi_C(\mathbf{x}_C) \]
MLE for Undirected GMs

• Today’s parameter estimation assumptions:
  1. The graphical model structure is given
  2. Every variable appears in the training examples
Questions

1. What does the **likelihood objective** accomplish?

2. Is likelihood the **right objective** function?

3. **How do we optimize** the objective function (i.e. learn)?

4. What **guarantees** does the optimizer provide?

5. (What is the **mapping from data → model**? In what ways can we incorporate our domain knowledge? How does this impact learning?)
Options for MLE of MRFs

• **Setting I:**
  \[ \psi_C(x_C) = \theta_C, x_C \]
  A. MLE by inspection (Decomposable Models)
  B. Iterative Proportional Fitting (IPF)

• **Setting II:**
  \[ \psi_C(x_C) = \exp(\theta \cdot f(x_C)) \]
  C. Generalized Iterative Scaling
  D. Gradient-based Methods
Today’s Lecture

• **Setting I:**
  \[ \psi_C(x_C) = \theta_C, x_C \]
  A. MLE by inspection (Decomposable Models)
  B. Iterative Proportional Fitting (IPF)

• **Setting II:**
  \[ \psi_C(x_C) = \exp(\theta \cdot f(x_C)) \]
  C. Generalized Iterative Scaling
  D. Gradient-based Methods
Options for MLE of MRFs

Whiteboard

- Derivative of log-likelihood with respect to potentials
**Discrete Variables (Tabular clique Potentials)**

- Remember categorical distribution
\[
p(x = t) \propto \prod_k \theta_k^{x=t}
\]

- Tabular clique potentials look like:
\[
\phi_c(\mathcal{X}_c^n) = \prod_{\mathcal{Y}_c} \phi_c(\mathcal{Y}_c)^{\mathbb{I}[\mathcal{Y}_c = \mathcal{X}_c^n]} 
\]

- Log likelihood function:
\[
L(\phi) = \sum_n \sum_c \sum_{\mathcal{Y}_c} \mathbb{I}[\mathcal{Y}_c = \mathcal{X}_c^n] \log \phi_c(\mathcal{Y}_c) - N \log Z(\phi)
\]
Whiteboard

• Derivative of log-likelihood for the tabular clique potentials

\[
L(\phi) = \sum_{n} \sum_{c} \sum_{Y_c} \mathbb{I}[Y_c = X_c^n] \log \phi_c(Y_c) - N \log Z(\phi) \quad Z(\phi) = \sum_{Y_c} \prod_{c} \phi_c(Y_c)
\]
Conditions on Clique Marginals

• Derivative of log-likelihood
  \[ \frac{\partial}{\partial \phi_c(\mathcal{Y}_c)} L(\theta) = \sum_n \mathbb{I} [\mathcal{Y}_c = \mathcal{X}_c^n] \frac{1}{\phi_c(\mathcal{Y}_c)} - N \frac{p(\mathcal{Y}_c)}{\phi_c(\mathcal{Y}_c)} \]

• Hence, for the maximum likelihood parameters, we know that:
  \[ p(\mathcal{X}_c) = \epsilon(\mathcal{X}_c) \]
  \[ \epsilon(\mathcal{X}_c) \equiv \frac{1}{N} \sum_{n=1}^{N} \mathbb{I} [\mathcal{X}_c = \mathcal{X}_c^n] \]

• In other words, at the maximum likelihood setting of the parameters, for each clique, the model marginals must be equal to the observed marginals (empirical counts).

• This doesn’t tell us how to get the ML parameters, it just gives us a condition that must be satisfied when we have them.
Options for MLE of MRFs

• **Setting I:**
  \[ \psi_C(x_C) = \theta_C, x_C \]

  A. MLE by inspection (Decomposable Models) – easy cases
  B. Iterative Proportional Fitting (IPF)

• **Setting II:**
  \[ \psi_C(x_C) = \exp(\theta \cdot f(x_C)) \]

C. Generalized Iterative Scaling
D. Gradient-based Methods
Decomposable Graphs

\[ p(x_1, \ldots, x_6) = \frac{1}{Z} \phi(x_1, x_2) \phi(x_2, x_3, x_5) \phi(x_2, x_4, x_5) \phi(x_5, x_6) \]
Decomposable Graphs

Remember this from Lectures 6

\[ p(x_1, \ldots, x_6) = \frac{1}{Z} \phi(x_1, x_2) \phi(x_3, x_4, x_5) \phi(x_5, x_6) \]

\[ p(a, b, c, d) = \frac{\phi(a, b, c) \phi(b, c, d)}{Z} = \frac{p(a, b, c)p(b, c, d)}{p(c, b)} \]
Decomposable Graphs

• **Definition:** Graph is **decomposable** if it can be recursively subdivided into sets $A$, $B$, and $S$ such that $S$ separates $A$ and $B$.

\[
p(x_1, \ldots, x_6) = \frac{1}{Z} \phi(x_1, x_2) \phi(x_2, x_3) \]

\[
p(\mathcal{X}) = \frac{\prod_c p(\mathcal{X}_c)}{\prod_s p(\mathcal{X}_s)}
\]
Decomposable Graphs

\[ p(x_1, \ldots, x_6) = \frac{1}{Z} \phi(x_1, x_2) \phi(x_2, x_3, x_5) \phi(x_2, x_4, x_5) \phi(x_5, x_6) \]

\[ p(x_1, \ldots, x_6) = \frac{p(x_1, x_2)p(x_2, x_3, x_5)p(x_2, x_4, x_5)p(x_5, x_6)}{p(x_2)p(x_2, x_5)p(x_5)} \]

\[ p(x_1, \ldots, x_6) = \frac{p(x_1|x_2)p(x_2, x_3, x_5)p(x_4|x_2, x_5)p(x_6|x_5)}{\phi(x_1, x_2) \phi(x_2, x_3, x_5) \phi(x_2, x_4, x_5) \phi(x_5, x_6)} \]

\[ L = \sum_n \log p(x_1^n|x_2^n) + \log p(x_2^n, x_3^n, x_5^n) + \log p(x_4^n|x_2^n, x_5^n) + \log p(x_6^n|x_5^n) \]

\[ \phi(x_1, x_2) = \epsilon(x_1|x_2), \quad \phi(x_2, x_3, x_5) = \epsilon(x_2, x_3, x_5), \quad \phi(x_2, x_4, x_5) = \epsilon(x_4|x_2, x_5), \quad \phi(x_5, x_6) = \epsilon(x_6|x_5) \]
MLE by Guessing

• **Definition:** Graph is *decomposable* if it can be recursively subdivided into sets A, B, and S such that S separates A and B.

• **Recipe for MLE by Guessing:**
  – Three conditions:
    1. Graphical model is *decomposable*
    2. Potentials defined on *maximal cliques*
    3. Potentials are parameterized as: \( \psi_C(x_C) = \theta_{C,x_C} \)
  – **Step 1:** set each clique potential to its empirical marginal
  – **Step 2:** divide out every non-empty intersection between cliques *exactly once*
Non-decomposable and/or with non-maximal clique potentials

- If the graph is non-decomposable, and or the potentials are defined on non-maximal cliques (e.g., $\psi_{12}$, $\psi_{34}$), we could not equate empirical marginals (or conditionals) to MLE of cliques potentials.

\[
p(x_1, x_2, x_3, x_4) = \prod_{\{i,j\}} \psi_{ij}(x_i, x_j)
\]

\[
\exists (i,j) \text{ s.t. } \psi_{ij}^{\text{MLE}}(x_i, x_j) \neq \begin{cases} \tilde{p}(x_i, x_j) / \tilde{p}(x_i) \\ \tilde{p}(x_i, x_j) / \tilde{p}(x_j) \end{cases}
\]
Options for MLE of MRFs

• Setting I:
  \[ \psi_C(x_C) = \theta_C, x_C \]
  A. MLE by inspection (Decomposable Models)
  B. Iterative Proportional Fitting (IPF)

• Setting II:
  \[ \psi_C(x_C) = \exp(\theta \cdot f(x_C)) \]
  C. Generalized Iterative Scaling
  D. Gradient-based Methods
Fixed Point Iteration for Optimization

- Fixed point iteration is a general tool for solving systems of equations
- It can also be applied to optimization.

<table>
<thead>
<tr>
<th>$J(\theta)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\frac{dJ(\theta)}{d\theta_i} = 0 = f(\theta)$</td>

</table>

1. Given objective function:
2. Compute derivative, set to zero (call this function $f$).
3. Rearrange the equation s.t. one of parameters appears on the LHS.
4. Initialize the parameters.
5. For $i$ in $\{1,...,K\}$, update each parameter and increment $t$:
6. Repeat #5 until convergence
Fixed Point Iteration for Optimization

• Fixed point iteration is a general tool for solving systems of equations
• It can also be applied to optimization.

1. Given objective function:

2. Compute derivative, set to zero (call this function $f$).

3. Rearrange the equation s.t. one of parameters appears on the LHS.

4. Initialize the parameters.

5. For $i$ in $\{1,...,K\}$, update each parameter and increment $t$:

6. Repeat #5 until convergence

\[ J(x) = \frac{x^3}{3} + \frac{3}{2}x^2 + 2x \]

\[ \frac{dJ(x)}{dx} = f(x) = x^2 - 3x + 2 = 0 \]

\[ \Rightarrow x = \frac{x^2 + 2}{3} = g(x) \]

\[ x \leftarrow \frac{x^2 + 2}{3} \]
Fixed Point Iteration for Optimization

We can implement our example in a few lines of python.

\[
J(x) = \frac{x^3}{3} + \frac{3}{2}x^2 + 2x
\]

\[
\frac{dJ(x)}{dx} = f(x) = x^2 - 3x + 2 = 0
\]

\[
\Rightarrow x = \frac{x^2 + 2}{3} = g(x)
\]

\[
x \leftarrow \frac{x^2 + 2}{3}
\]
Fixed Point Iteration for Optimization

$\texttt{python fixed-point-iteration.py}$

\begin{align*}
i &= 0 \quad &x &= 0.0000 \quad &f(x) &= 2.0000 \\

i &= 20 \quad &x &= 0.9999 \quad &f(x) &= 0.0001
\end{align*}

\[
J(x) = \frac{x^3}{3} + \frac{3}{2} x^2 + 2x
\]

\[
\frac{dJ(x)}{dx} = f(x) = x^2 - 3x + 2 = 0
\]

\[
\Rightarrow x = \frac{x^2 + 2}{3} = g(x)
\]

\[
x \leftarrow \frac{x^2 + 2}{3}
\]
Iterative Proportional Fitting (IPF)

IPF applies fixed point iteration to the derivative of the likelihood objective

\[ L(D; \phi) = \sum_{n=1}^{N} \log p(X^n; \phi) \]

\[ \frac{\partial}{\partial \phi_c(Y_c)} L(\theta) = \sum_n \mathbb{1}[Y_c = X^n_c] \frac{1}{\phi_c(Y_c)} - N \frac{p(Y_c)}{\phi_c(Y_c)} \]

\[ \phi_c(Y_c) = \frac{\epsilon(Y_c)}{p(Y_c)} \]

\[ \phi_c^{(t+1)}(Y_c) \leftarrow \phi_c^{(t)}(Y_c) \frac{\epsilon(Y_c)}{p^{(t)}(Y_c)} \]

1. Given likelihood objective
2. Compute derivative, set to zero
3. Rearrange the equation s.t. one of potentials appears on the LHS.
4. Initialize the potential tables.
5. For each clique \( c \) in \( C \), update each potential table and increment \( t \):
6. Repeat #5 until convergence

\[ p^{(t)}(Y_c) = \sum_{Y' : Y'_c = Y_c} p(Y'; \theta^{(t)}) \]
Properties of IPF Updates

- Applies only when potentials are parameterized as:
  \[ \psi_C(x_C) = \theta_C, x_C \]

- IPF iterates a set of fixed-point equations:
  \[ \phi^{(t+1)}_c(Y_c) \leftarrow \phi^{(t)}_c(Y_c) \frac{e(Y_c)}{p^{(t)}(Y_c)} \]

- However, we can prove it is also a coordinate ascent algorithm (coordinates = parameters of clique potentials).

- Hence at each step, it will increase the log-likelihood, and it will converge to a global maximum.
Options for MLE of MRFs

• **Setting I:**
  \[ \psi_C(x_C) = \theta_C, x_C \]
  A. MLE by inspection (Decomposable Models)
  B. Iterative Proportional Fitting (IPF)

• **Setting II:**
  \[ \psi_C(x_C) = \exp(\theta \cdot f(x_C)) \]
  C. Generalized Iterative Scaling
  D. Gradient-based Methods
Feature-based Clique Potentials

- So far we have discussed the most general form of an undirected graphical model in which cliques are parameterized by general “tabular” potential functions $\psi_c(x_c)$.
- But for large cliques these general potentials are exponentially costly for inference and have exponential numbers of parameters that we must learn from limited data.
- One solution is to change the graphical model to make cliques smaller. But this changes the dependencies, and may force us to make more independence assumptions than we would like.
- Another solution: keep the same graphical model, but use a less general parameterization of the clique potentials.
- This is the idea behind feature-based models.
Features

- Consider a clique \( x_c \) of random variables in a UGM, e.g. three consecutive characters \( c_1c_2c_3 \) in a string of English text.

- How would we build a model of \( p(c_1c_2c_3) \)?
  - If we use a single clique function over \( c_1c_2c_3 \), the full joint clique potential would be huge: \( 26^3 - 1 \) parameters.
  - However, we often know that some particular joint settings of the variables in a clique are quite likely or quite unlikely. e.g. ing, ate, ion, ?ed, qu?, jkx, zzz,...

- A “feature” is a function which is vacuous over all joint settings except a few particular ones on which it is high or low.
  - For example, we might have \( f_{\text{ing}}(c_1c_2c_3) \) which is 1 if the string is ‘ing’ and 0 otherwise, and similar features for ‘?ed’, etc.

- We can also define features when the inputs are continuous. Then the idea of a cell on which it is active disappears, but we might still have a compact parameterization of the feature.
Features as Micropotentials

- By exponentiating them, each feature function can be made into a “micropotential”. We can multiply these micropotentials together to get a clique potential.
- Example: a clique potential \( \psi(c_1c_2c_3) \) could be expressed as:

\[
\psi_c(c_1, c_2, c_3) = e^{\theta_{\text{ling}}f_{\text{ling}}} \times e^{\theta_{\text{red}}f_{\text{red}}} \times \ldots
\]

\[
= \exp\left\{ \sum_{k=1}^{K} \theta_k f_k(c_1, c_2, c_3) \right\}
\]

- This is still a potential over \( 26^3 \) possible settings, but only uses \( K \) parameters if there are \( K \) features.
  - By having one indicator function per combination of \( x_c \), we recover the standard tabular potential.
Combining Features

- Each feature has a weight $\theta_k$ which represents the numerical strength of the feature and whether it increases or decreases the probability of the clique.

- The marginal over the clique is a generalized exponential family distribution, actually, a GLM:

$$p(c_1, c_2, c_3) \propto \exp \left\{ \theta_{\text{ing}} f_{\text{ing}}(c_1, c_2, c_3) + \theta_{\text{ed}} f_{\text{ed}}(c_1, c_2, c_3) + \theta_{\text{qu?}} f_{\text{qu?}}(c_1, c_2, c_3) + \theta_{\text{zzz}} f_{\text{zzz}}(c_1, c_2, c_3) + \cdots \right\}$$

- Freedom in designing: In general, the features may be overlapping, unconstrained indicators or any function of any subset of the clique variables:

$$\psi_c(x_c) \overset{\text{def}}{=} \exp \left\{ \sum_{i \in I_c} \theta_k f_k(x_c) \right\}$$
We can multiply these clique potentials as usual:

\[ p(x) = \frac{1}{Z(\theta)} \prod_c \psi_c(x_c) = \frac{1}{Z(\theta)} \exp \left\{ \sum_c \sum_{i \in I_c} \theta_k f_k(x_{c_i}) \right\} \]

However, in general we can forget about associating features with cliques and just use a simplified form:

\[ p(x) = \frac{1}{Z(\theta)} \exp \left\{ \sum_i \theta_i f_i(x_{c_i}) \right\} \]

This is just our friend the **exponential family model**, with the features as sufficient statistics!

Learning: recall that in IPF, we have

\[ \phi_c^{(t+1)}(Y_c) \propto \phi_c^{(t)}(Y_c) \frac{e(Y_c)}{p(t)(Y_c)} \]

Not obvious how to use this rule to update the weights and features individually !!!
Options for MLE of MRFs

• **Setting I:**
  \[ \psi_C(x_C) = \theta_C, x_C \]
  
  A. MLE by inspection (Decomposable Models)
  
  B. Iterative Proportional Fitting (IPF)

• **Setting II:**
  \[ \psi_C(x_C) = \exp(\theta \cdot f(x_C)) \]
  
  C. Generalized Iterative Scaling
  
  D. Gradient-based Methods
Generalized Iterative Scaling (GIS)

Key idea:

– Define a function which lower-bounds the log-likelihood
– Observe that the bound is tight at current parameters
– Increase lower-bound by fixed-point iteration in order to increase log-likelihood

Side note: This idea is akin to a standard derivation of the Expectation-Maximization (EM) algorithm
Generalized Iterative Scaling (GIS)

GIS applies fixed point iteration to the derivative of a lower-bound of the likelihood objective.

\[ L(D; \theta) = \sum_{n=1}^{N} \log p(X^n; \theta) \]

\[ L(D; \theta) \geq \Lambda(\theta) \]

\[ \frac{\partial \Lambda(\theta_c)}{\partial \theta_c} = \frac{1}{N} \sum_{n} f_c(X^n) - \mathbb{E} \left[ f_c(X_c) \exp \left( (\theta_c - \theta_{old}) \sum_{d} f_d(X_d) \right) \right] \]

\[ \theta^{t+1} \leftarrow \theta^t + \log \left( \frac{1/N \sum_n f(X^n)}{\mathbb{E} [f_c(X_c)]} \right) \]

1. Given avg. likelihood objective
2. Derive lower bound
3. Compute derivative of bound, set to zero
4. Rearrange the equation s.t. one parameter appears on the LHS.
5. Initialize the parameters.
6. For each \( i \) in \( \{1,...,K\} \), update each parameter and increment \( t \):
7. Repeat #6 until convergence

The lower bound is obtained by linearizing a log and applying Jensen-Shannon.
Contrast of IPF and GIS

- **IPF**
  - a general algorithm for finding MLE of UGMs.
  - a **fixed-point equation** for $\psi_c$ over single cliques, coordinate ascent
  - Requires the potential to be fully parameterized
  - The clique described by the potentials do not have to be max-clique
  - For fully decomposable model, reduces to a single step iteration

- **GIS**
  - Iterative scaling on general UGM with feature-based potentials
  - IPF is a special case of GIS which the clique potential is built on features defined as an indicator function of clique configurations.

\[
\theta^{t+1} \leftarrow \theta^t + \log \left( \frac{1}{N} \sum_n f(X^n_c) \right)
\]

\[
\phi^{(t+1)}_c(Y_c) \leftarrow \phi^{(t)}_c(Y_c) \frac{e(Y_c)}{p^{(t)}(Y_c)}
\]
Options for MLE of MRFs

• **Setting I:**
  \[ \psi_C(x_C) = \theta_C x_C \]
  
  A. MLE by inspection (Decomposable Models)
  B. Iterative Proportional Fitting (IPF)

• **Setting II:**
  \[ \psi_C(x_C) = \exp(\theta \cdot f(x_C)) \]
  
  C. Generalized Iterative Scaling
  D. Gradient-based Methods
Recipe for Gradient-based Learning

1. Write down the objective function
2. Compute the partial derivatives of the objective (i.e. gradient, and maybe Hessian)
3. Feed objective function and derivatives into black box
4. Retrieve optimal parameters from black box
Optimization Algorithms

What is the black box?

• Newton’s method
• Hessian-free / Quasi-Newton methods
  – Conjugate gradient
  – L-BFGS
• Stochastic gradient methods
  – Stochastic gradient descent (SGD)
  – Stochastic meta-descent
  – AdaGrad
Suppose we want to find the maximum likelihood parameters:

The log-likelihood is then:

The likelihood of all these is:

Let

Recall the pdf of the Categorical distribution:

Gradient Descent:

This implies that

Suppose we have

Optimization has nearly become a technology. Almost every language has many generic small (e.g. Limited memory BFGS stores only a history of the last quasi-Newton methods approximate the Hessian.

What if we have \( n = \) millions of features?

In most presentations, Newton-Raphson would be presented a

Intuition:

From our introductory example, we know that we can find the solution to a quadratic function analytically. Yet gradient descent may take many steps to converge to that optimum. The motivation behind Newton's method is to use a quadratic approximation of our function to make a good guess where we should step next.

Consider the second order Taylor series expansion of

Definition: the Hessian of an

What if we have

Distribution:

For CRF training Stochastic Meta Descent is even better (Vishwanathan, 2006).

SGD Algorithm:

1. Choose a starting point \( x \).
2. While not converged:
   - Choose a step size \( t \).
   - Choose \( i \) so that it sweeps through the training set.
   - Update
     \[
     \tilde{x}^{(k+1)} = \tilde{x}^{(k)} + t \nabla f_i(\tilde{x})
     \]
Whiteboard

Summary

A. **MLE by inspection** (Decomposable Models)
   - Very limited applicability
   - Exemplifies the need for general algorithms

B. **Iterative Proportional Fitting (IPF)**
   - Guaranteed to converge
   - Only applies to “tabular” potential functions

A. **Generalized Iterative Scaling (GIS)**
   - Maximizes a lower-bound of log-likelihood
   - Iterative algorithm (like IPF), but more broadly applies to exponential family potentials
   - When $\sum_c f(X_c) = 1$ has an advantage

B. **Gradient-based Methods**
   - Doesn’t require fancy optimization algorithms (i.e. SGD works great)
   - Faster convergence than GIS
   - Applies to arbitrary potentials [later in the course]
MLE for Undirected GMs

1. Data

\[ \mathcal{D} = \{ \mathbf{x}^{(n)} \}_{n=1}^{N} \]

2. Model

\[ p(\mathbf{x} | \theta) = \frac{1}{Z(\theta)} \prod_{C \in \mathcal{C}} \psi_C(\mathbf{x}_C) \]

3. Objective

\[ \ell(\theta; \mathcal{D}) = \sum_{n=1}^{N} \log p(\mathbf{x}^{(n)} | \theta) \]

4. Learning

\[ \theta^* = \text{argmax}_{\theta} \ell(\theta; \mathcal{D}) \]

5. Inference

1. Marginal Inference

\[ p(\mathbf{x}_C) = \sum_{\mathbf{x}': \mathbf{x}'_C = \mathbf{x}_C} p(\mathbf{x}' | \theta) \]

2. Partition Function

\[ Z(\theta) = \sum_{\mathbf{x}} \prod_{C \in \mathcal{C}} \psi_C(\mathbf{x}_C) \]
Contrast of MLE for directed / undirected GMs

- For **directed** graphical models, the log-likelihood decomposes into a sum of terms, one per family (node plus parents).
- For **undirected** graphical models, the log-likelihood does not decompose, because the normalization constant $Z$ is a function of all the parameters.

\[
P(x_1, \ldots, x_n) = \frac{1}{Z} \prod_{c \in C} \psi_c(x_c) \quad \quad Z = \sum_{x_1, \ldots, x_n} \prod_{c \in C} \psi_c(x_c)
\]

- In general, we will need to do inference (i.e., marginalization) to learn parameters for undirected models, even in the fully observed case.
5. Inference

Three Tasks:

1. **Marginal Inference**
Compute marginals of variables and cliques

\[
p(x_i) = \sum_{x' : x'_i = x_i} p(x' \mid \theta) \quad \text{and} \quad p(x_C) = \sum_{x' : x'_C = x_C} p(x' \mid \theta)
\]

2. **Partition Function**
Compute the normalization constant

\[
Z(\theta) = \sum_x \prod_{C \in \mathcal{C}} \psi_C(x_C)
\]

3. **MAP Inference**
Compute variable assignment with highest probability

\[
\hat{x} = \arg\max_x p(x \mid \theta)
\]

Next time: How to compute these!
ML Structural Learning via Neighborhood Selection for completely observed MRF
Gaussian Graphical Models

- Multivariate Gaussian density:

\[
p(x | \mu, \Sigma) = \frac{1}{(2\pi)^{n/2} |\Sigma|^{1/2}} \exp\left\{ -\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu) \right\}
\]

- WOLG: let \( \mu = 0 \) \( Q = \Sigma^{-1} \)

\[
p(x_1, x_2, \ldots, x_p | \mu = 0, Q) = \frac{|Q|^{1/2}}{(2\pi)^{n/2}} \exp\left\{ -\frac{1}{2} \sum_i q_{ii} (x_i)^2 - \sum_{i<j} q_{ij} x_i x_j \right\}
\]

- We can view this as a continuous Markov Random Field with potentials defined on every node and edge:
Pairwise MRF (e.g., Ising Model)

- Assuming the nodes are discrete, and edges are weighted, then for a sample $x_d$, we have

\[
P(x_d|\Theta) = \exp \left( \sum_{i \in V} \theta_i^t x_{d,i} + \sum_{(i,j) \in E} \theta_{ij} x_{d,i} x_{d,j} - A(\Theta) \right)
\]
The covariance and the precision matrices

- **Covariance matrix**
  \[ \sum_{i,j} = 0 \implies X_i \perp X_j \quad \text{or} \quad p(X_i, X_j) = p(X_i)p(X_j) \]
  
  - Graphical model interpretation?

- **Precision matrix**
  \[ Q = \sum^{-1} \]
  \[ Q_{i,j} = 0 \implies X_i \perp X_j \mid X_{-ij} \quad \text{or} \quad p(X_i, X_j \mid X_{-ij}) = p(X_i \mid X_{-ij})p(X_j \mid X_{-ij}) \]
  
  - Graphical model interpretation?
Sparse precision vs. sparse covariance in GGM

\[
\Sigma^{-1} = \begin{pmatrix}
1 & 6 & 0 & 0 & 0 \\
6 & 2 & 7 & 0 & 0 \\
0 & 7 & 3 & 8 & 0 \\
0 & 0 & 8 & 4 & 9 \\
0 & 0 & 0 & 9 & 5
\end{pmatrix}
\]

\[
\Sigma = \begin{pmatrix}
0.10 & 0.15 & -0.13 & -0.08 & 0.15 \\
0.15 & -0.03 & 0.02 & 0.01 & -0.03 \\
-0.13 & 0.02 & 0.10 & 0.07 & -0.12 \\
-0.08 & 0.01 & 0.07 & -0.04 & 0.07 \\
0.15 & -0.03 & -0.12 & 0.07 & 0.08
\end{pmatrix}
\]

\[
\Sigma_{15}^{-1} = 0 \iff X_1 \perp X_5 \mid X_{nbrs(1) \text{ or } nbers(5)}
\]

\[
X_1 \perp X_5 \iff \Sigma_{15} = 0
\]
Another example

- How to estimate this MRF?
- What if $p \gg n$
  - MLE does not exist in general!
  - What about only learning a “sparse” graphical model?
    - This is possible when $s=o(n)$
    - Very often it is the structure of the GM that is more interesting …
Recall lasso

\[ \hat{\theta}_i = \arg \min_{\theta_i} l(\theta_i) + \lambda_1 \| \theta_i \|_1 \]

where \( l(\theta_i) = \log P(y_i|x_i, \theta_i) \).
Graph Regression

Neighborhood selection

Lasso:

\[ \hat{\theta} = \arg\min_{\theta} \sum_{t=1}^{T} l(\theta) + \lambda_1 \| \theta \|_1 \]
It can be shown that: given *iid* samples, and under several technical conditions (e.g., "irrepresentable"), the recovered structured is "sparsistent" even when $p >> n$. 
Learning Ising Model
(i.e. pairwise MRF)

- Assuming the nodes are discrete, and edges are weighted, then for a sample \(x_d\), we have

\[
P(x_d|\Theta) = \exp\left(\sum_{i \in V} \theta_{ii}^t x_{d,i} + \sum_{(i,j) \in E} \theta_{ij} x_{d,i} x_{d,j} - A(\Theta)\right)
\]

- It can be shown following the same logic that we can use L_1 regularized logistic regression to obtain a sparse estimate of the neighborhood of each variable in the discrete case.
Consistency

- **Theorem**: for the graphical regression algorithm, under certain verifiable conditions (omitted here for simplicity):

\[ P \left[ \hat{G}(\lambda_n) \neq G \right] = O \left( \exp \left( -C n^\epsilon \right) \right) \to 0 \]

Note the from this theorem one should see that the regularizer is not actually used to introduce an “artificial” sparsity bias, but a devise to ensure consistency under finite data and high dimension condition.
